

## Notes

The project is conducted with a Jetson Orin Nano Developer Kit 8GB. It originally started with Jetson firmware 4.1 causing a different boot up than the one recommended.

### 1.1 Recommended First Boot: Flashing Jetpack Jetson Orin Nano Developer Kit Using Ethcher

This will depend on what firmware version is on the Jetson Board.

To prepare your microSD card, you'll need a computer with Internet connection and the ability to read and write SD cards, either via a built-in SD card slot or adapter.

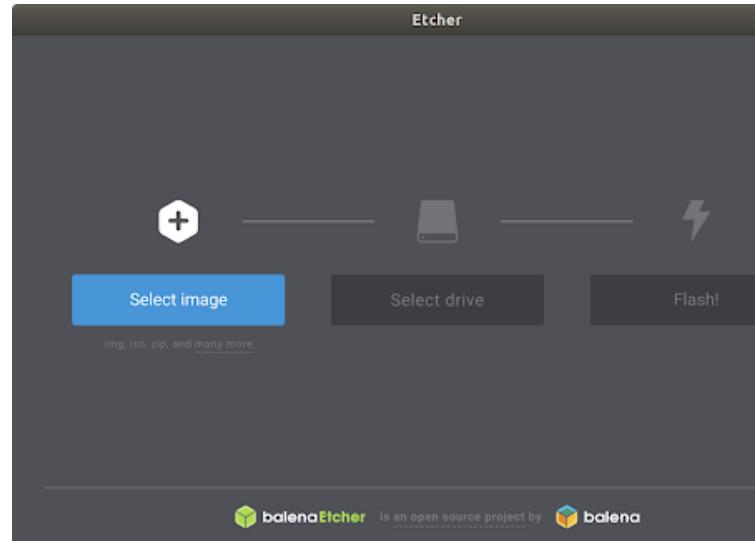

1. Download the Jetson Orin Nano Developer Kit SD Card image from JetPack SDK Page , and note where it was saved on the computer.
  - Before writing the sd card go to the disc manager and ensure that there are no partitions on the sd card you will not need to worry about this with a new sd card
2. Write the image to your microSD card by following the instructions here according to the type of computer you are using: Windows, Mac, or Linux.

**Use the following instructions to download Ether**

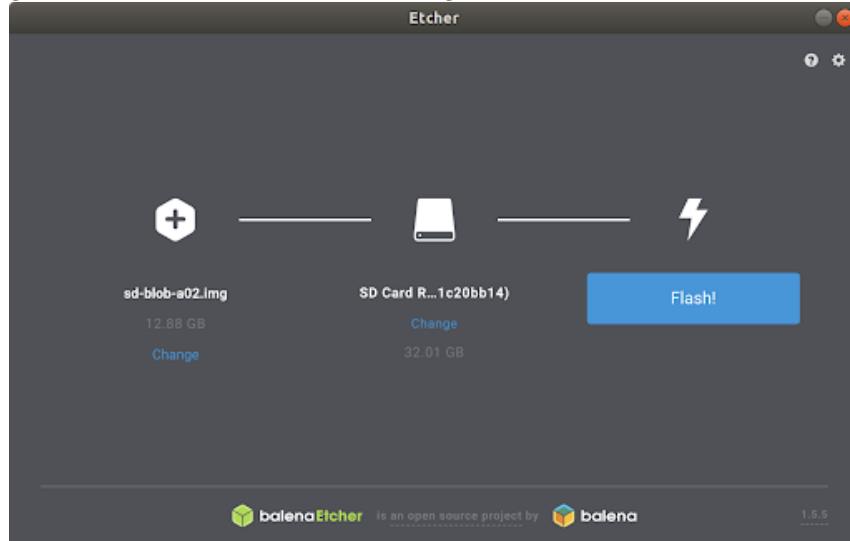

#### **Instructions for Linux**

You can either write the SD card image using a graphical program like Etcher, or via command line.

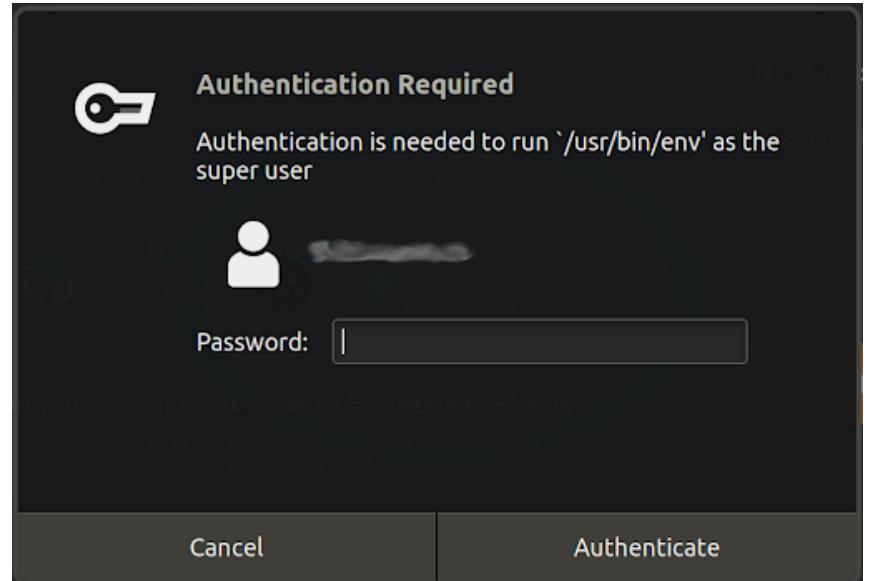

## **Etcher Instructions**

1. Download, install, and launch Etcher.
2. Click “Select image” and choose the zipped image file downloaded earlier.
3. Insert your microSD card. If you have no other external drives attached, Etcher will automatically select the microSD card as target device. Otherwise, click “Change” and choose the correct device.

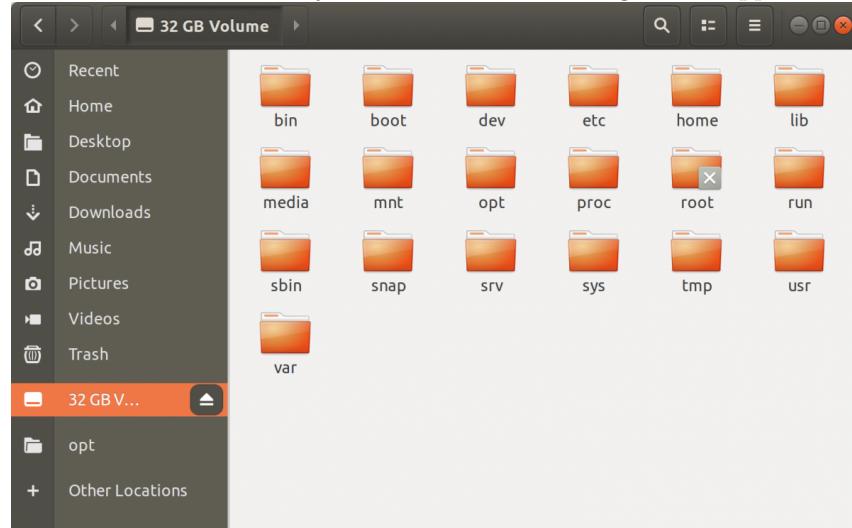

4. Click “Flash!” Your OS may prompt for your username and password before

it allows Etcher to proceed.

It will take Etcher 10-15 minutes to write and validate the image if your microSD card is connected via USB3.

5. After Etcher finishes, eject the SD Card using Files application:

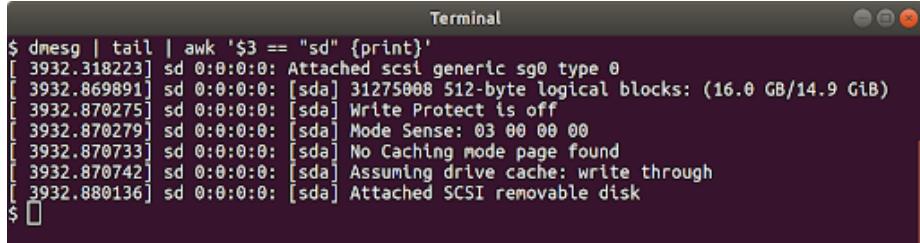

6. Physically remove microSD card from the computer.

## Command Line Instructions

1. Open the Terminal application by pressing **Ctrl + Alt + t**.
2. Insert your microSD card, then use a command like this to show which

disk device was assigned to it:

```
dmesg | tail | awk '$2 == "sd" {print}'
```

A terminal window titled "Terminal" showing the output of the command "dmesg | tail | awk '\$2 == \"sd\" {print}'". The output details the initialization of a SCSI generic sg0 type 0 disk, identifying it as [sda]. It shows 31275008 512-byte logical blocks (16.0 GB/14.9 GiB), Write Protect is off, Mode Sense: 03 00 00 00, No Caching mode page found, Assuming drive cache: write through, and it is an Attached SCSI removable disk.

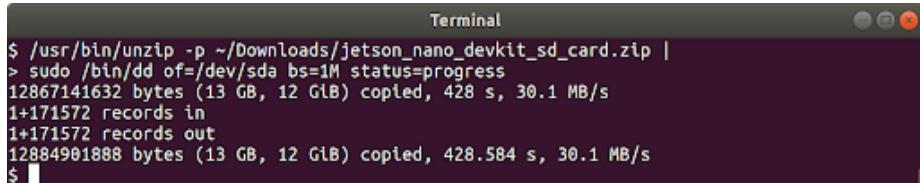

```
$ dmesg | tail | awk '$2 == "sd" {print}'  
[ 3932.318223] sd 0:0:0:0: Attached scsi generic sg0 type 0  
[ 3932.869891] sd 0:0:0:0: [sda] 31275008 512-byte logical blocks: (16.0 GB/14.9 GiB)  
[ 3932.870275] sd 0:0:0:0: [sda] Write Protect is off  
[ 3932.870279] sd 0:0:0:0: [sda] Mode Sense: 03 00 00 00  
[ 3932.870733] sd 0:0:0:0: [sda] No Caching mode page found  
[ 3932.870742] sd 0:0:0:0: [sda] Assuming drive cache: write through  
[ 3932.880136] sd 0:0:0:0: [sda] Attached SCSI removable disk  
$
```

Figure 1: alt text

3. Use this command to write the zipped SD card image to the microSD card:

```
/usr/bin/unzip -p ~/Downloads/jp60-orin-nano-sd-card-image.zip |  
sudo /bin/dd of=/dev/sda bs=1M status=progress
```

For example:

A terminal window titled "Terminal" showing the output of the command "/usr/bin/unzip -p ~/Downloads/jetson\_nano\_devkit\_sd\_card.zip | sudo /bin/dd of=/dev/sda bs=1M status=progress". The output shows the progress of the dd command, indicating 12867141632 bytes (13 GB, 12 GiB) copied at 428 s, 30.1 MB/s, with 1+171572 records in and 1+171572 records out. The total copied size is 12884901888 bytes (13 GB, 12 GiB) at 428.584 s, 30.1 MB/s.

```
$ /usr/bin/unzip -p ~/Downloads/jetson_nano_devkit_sd_card.zip |  
> sudo /bin/dd of=/dev/sda bs=1M status=progress  
12867141632 bytes (13 GB, 12 GiB) copied, 428 s, 30.1 MB/s  
1+171572 records in  
1+171572 records out  
12884901888 bytes (13 GB, 12 GiB) copied, 428.584 s, 30.1 MB/s  
$
```

Figure 2: alt text

When the dd command finishes, eject the disk device from the command line:  
`sudo eject /dev/sda`

4. Physically remove microSD card from the computer.

After your microSD card is ready, proceed to Setup your developer kit.

If this doesn't work use the Jetpack 5.1.3 instead of Jetpack 6.0. Use the following link

## Setup and First Boot

**Setup Steps** 1. Insert the microSD card (with system image already written to it) into the slot on the underside of the Jetson Orin Nano module. 2. Power on your computer display and connect it. 3. Connect the USB keyboard and mouse. 4. Connect the provided power supply. The Jetson Orin Nano Developer Kit will power on and boot automatically.

### First Boot

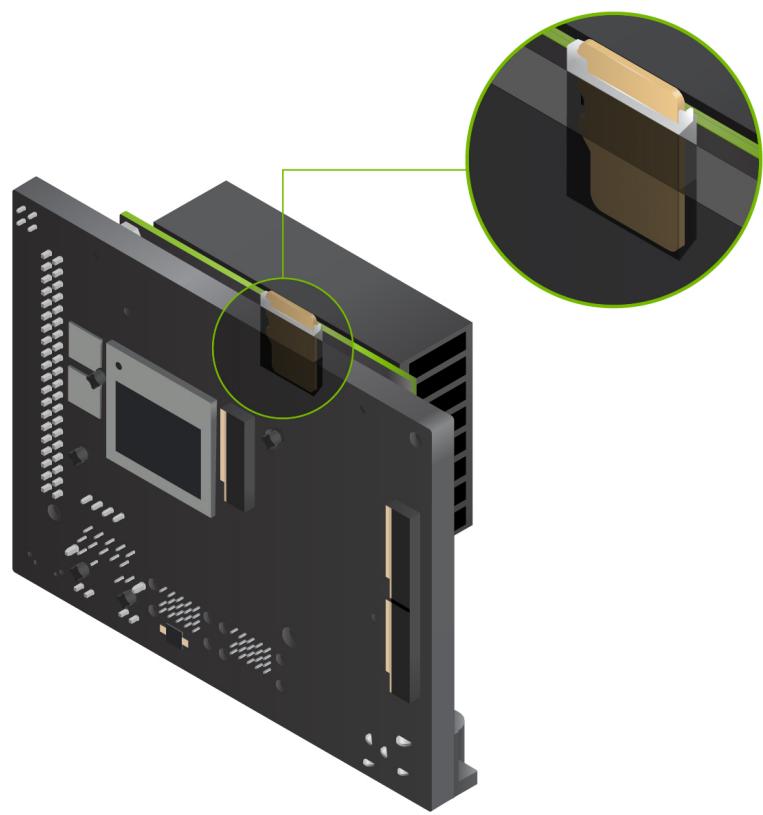

Figure 3: alt text

A green LED next to the USB-C connector will light as soon as the developer kit powers on. When you boot the first time, the Jetson Orin Nano Developer Kit will take you through some initial setup, including:

- Review and accept NVIDIA Jetson software EULA
- Select system language, keyboard layout, and time zone
- Connect to Wireless network
- Create username, password, and computer name
- Log in

**After Logging In** You will see this screen. Congratulations!

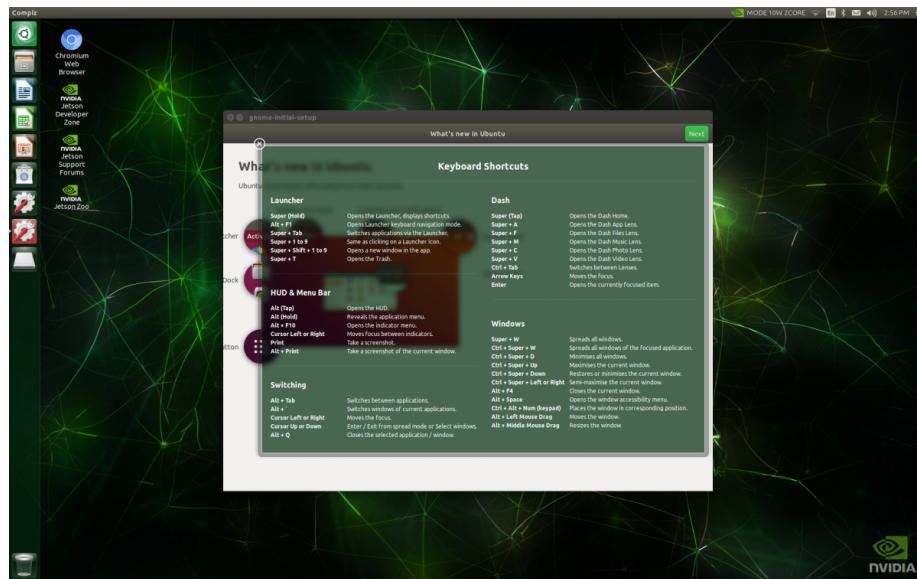

Figure 4: alt text

## 1.2 Flash to Jetpack +6.0 If Software Won't Update From 4.1 -> 5.1.3 -> +6.0

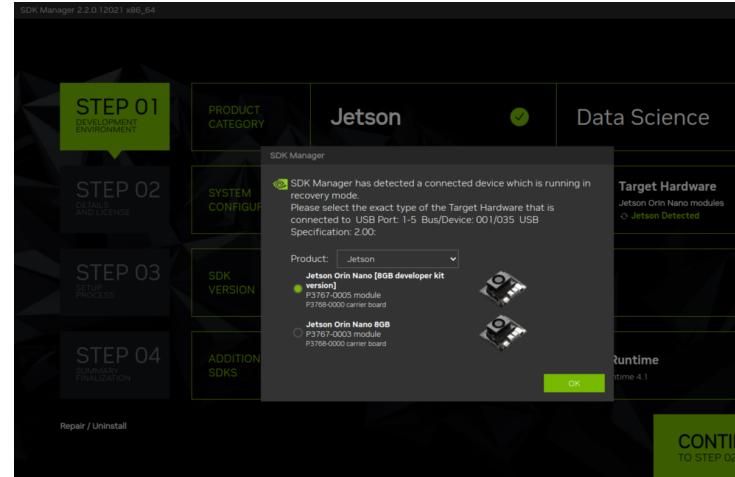

### Equipment needed

- Jetson Orin Nano Dev Kit
- Host PC running on **Ubuntu 20.04** with **Nvidia SDK Manager 2.2.0**
- 128 gb sc card
- 500 gb NVMe
- Nvidia Jetson Power cable (19.0V, 2.37A)
- Data capable usb to type-c
- Jumper wire
- Display with display port

- Display port cable
- Keyboard
- Mouse

## Hareware Setup

1. Install blank sd card and blank NVMe
2. Connect juper cable to put the Jetson in Force Recovery mode. (This enables the board to be detected by the SDK manager)
3. Connect the usb to host computer and the other end into the type-c port on the Jetson.
4. Connect the power source to the Jetson.
5. Open the SDK Manager (2.2.0 version ) on the Host computer (Ubuntu 20.04)

6. Select The Jetson Orin Nano Developer Kit  
#### Flushing Jetpack 5.1.3

Figure 5: alt text

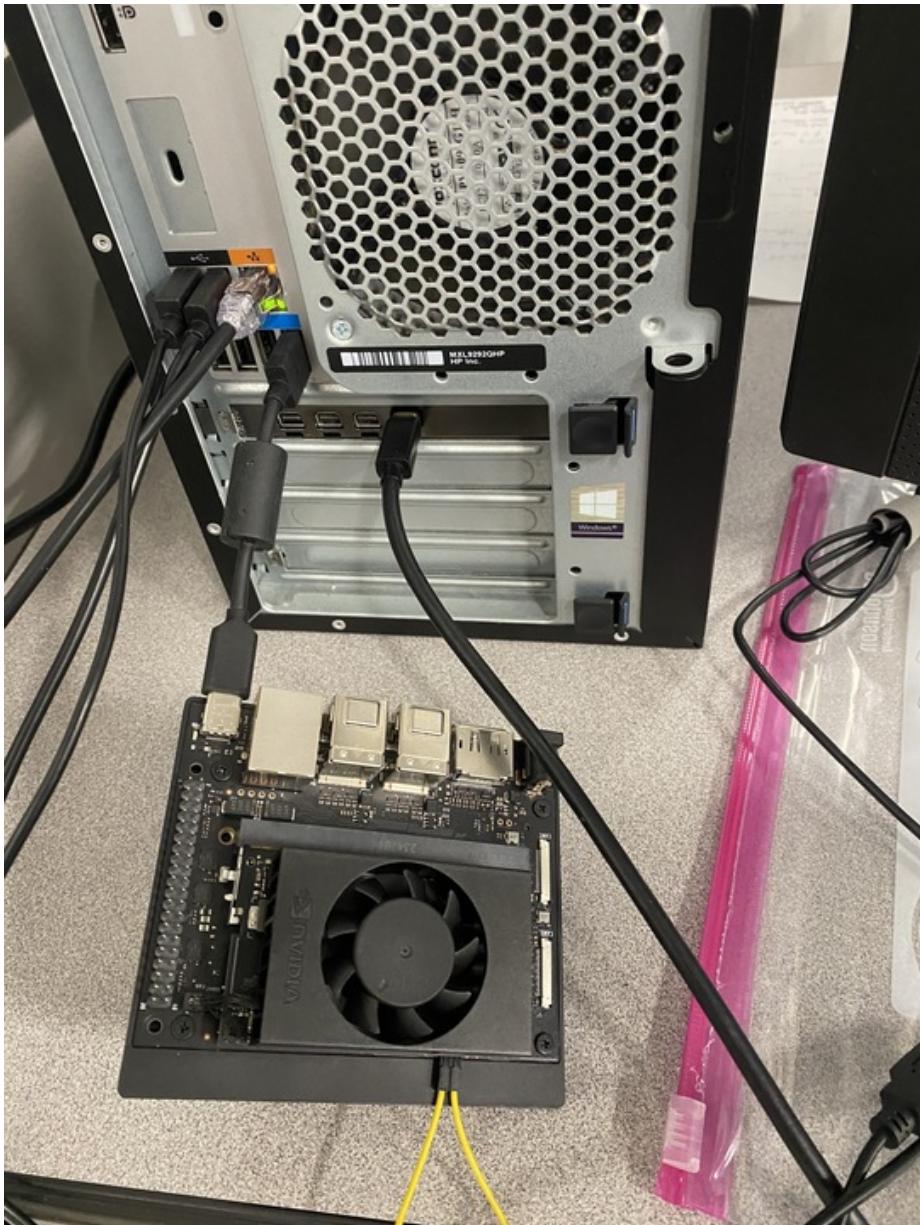

Figure 6: alt text

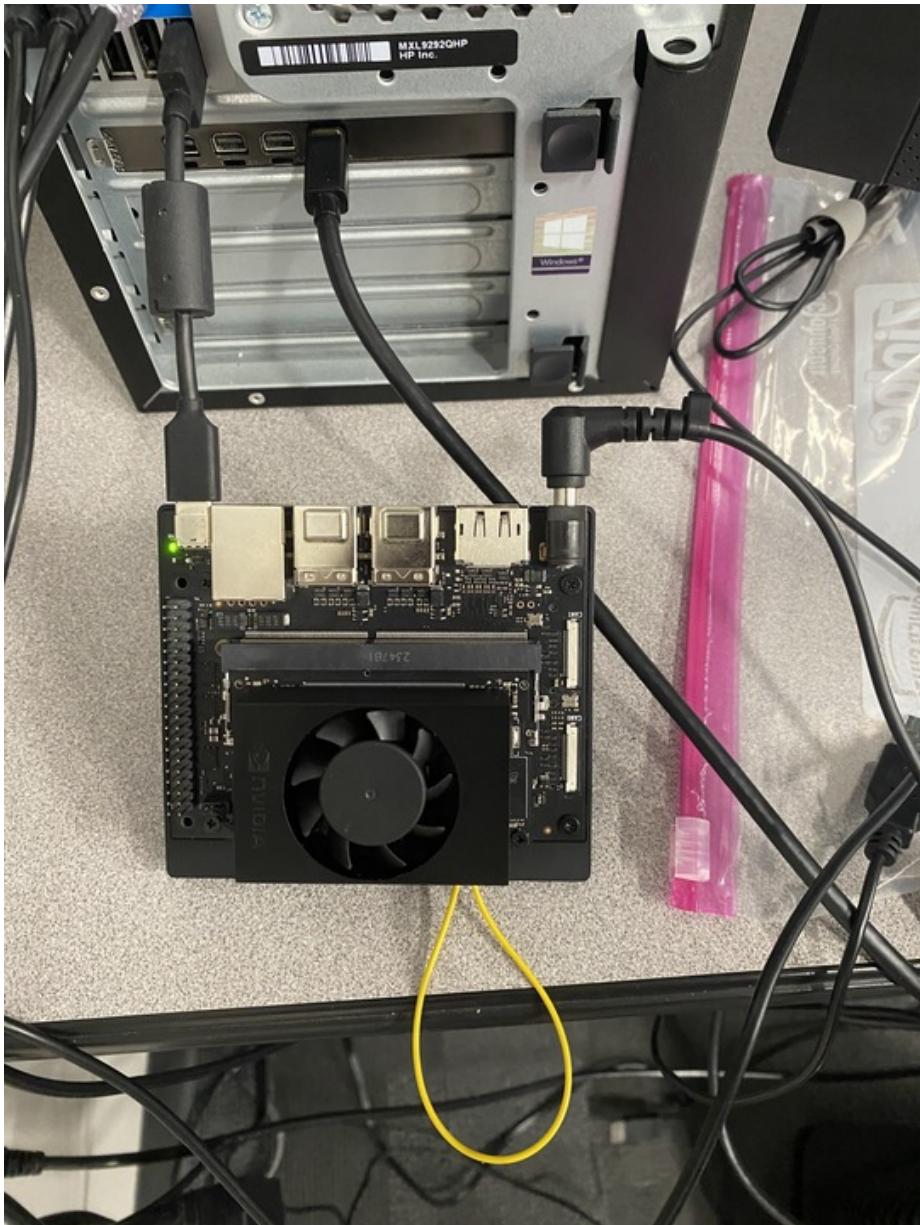

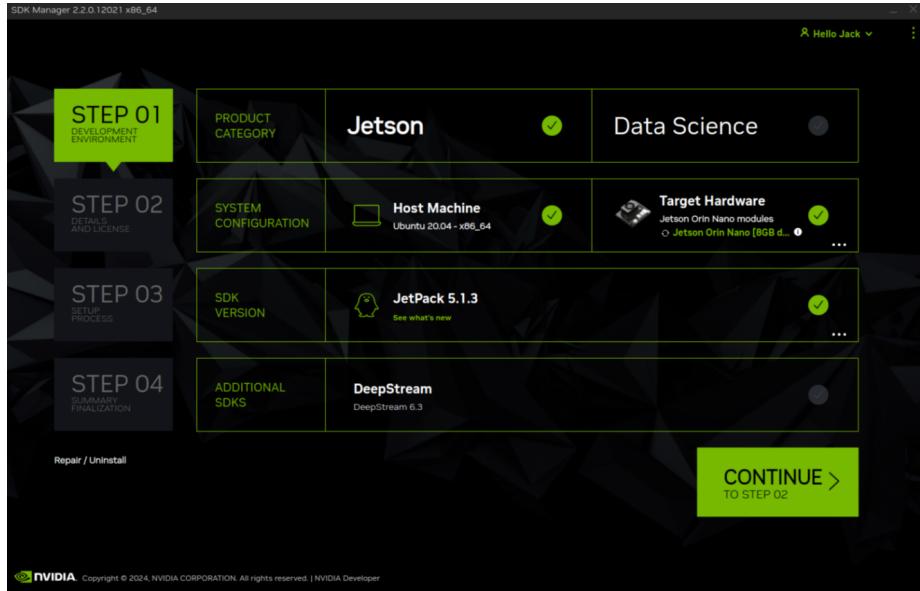

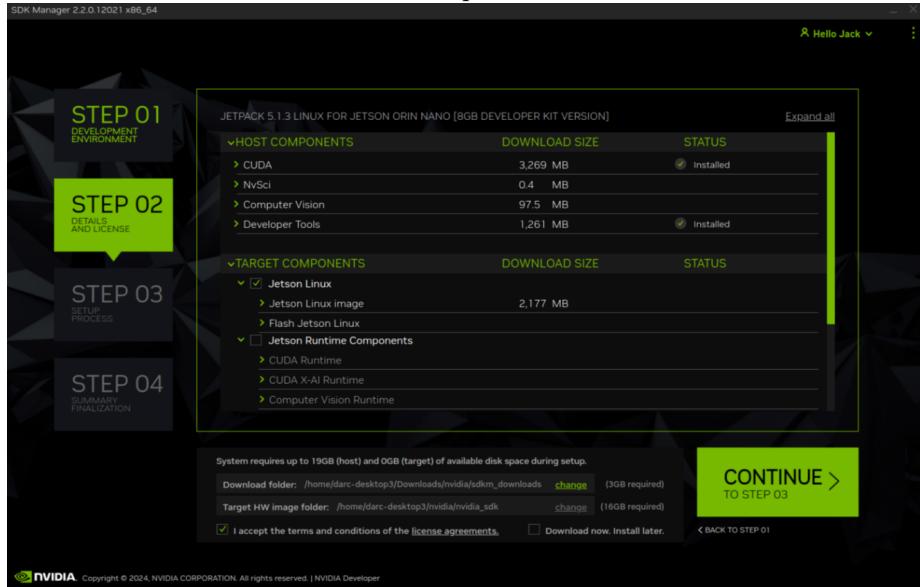

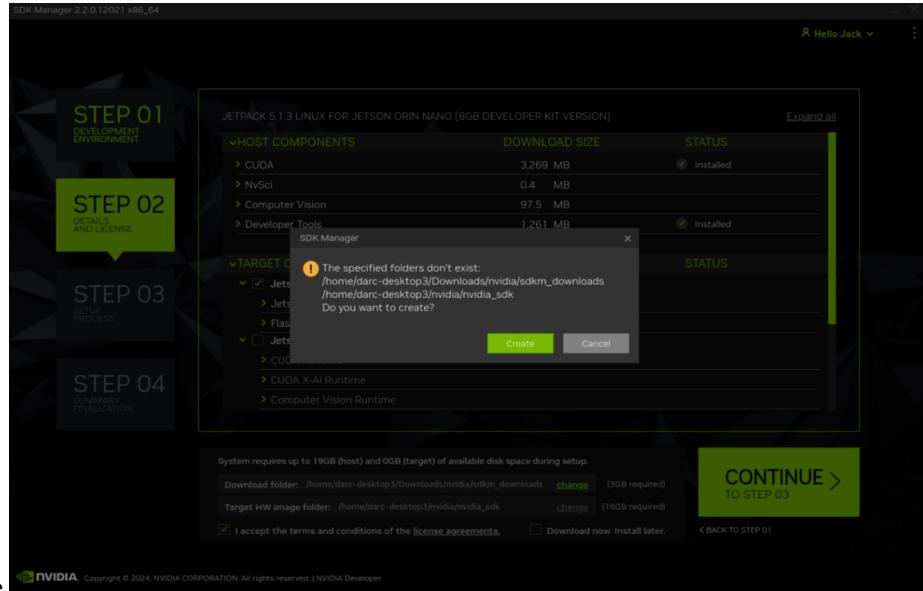

Figure 7: alt text

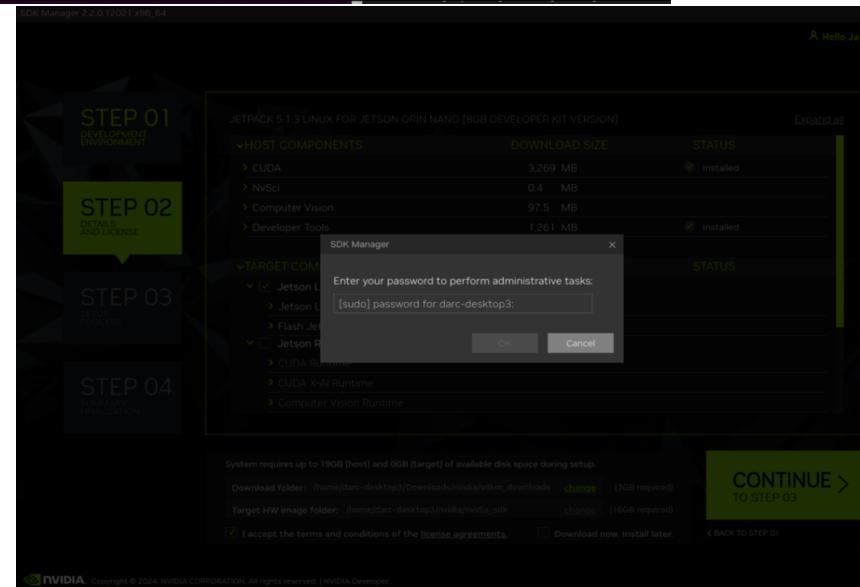

2. Continue to step 2 and **ONLY SELECT** Jetson Linux under TARGET COMPONENTS. As the other components are not needed at this time.

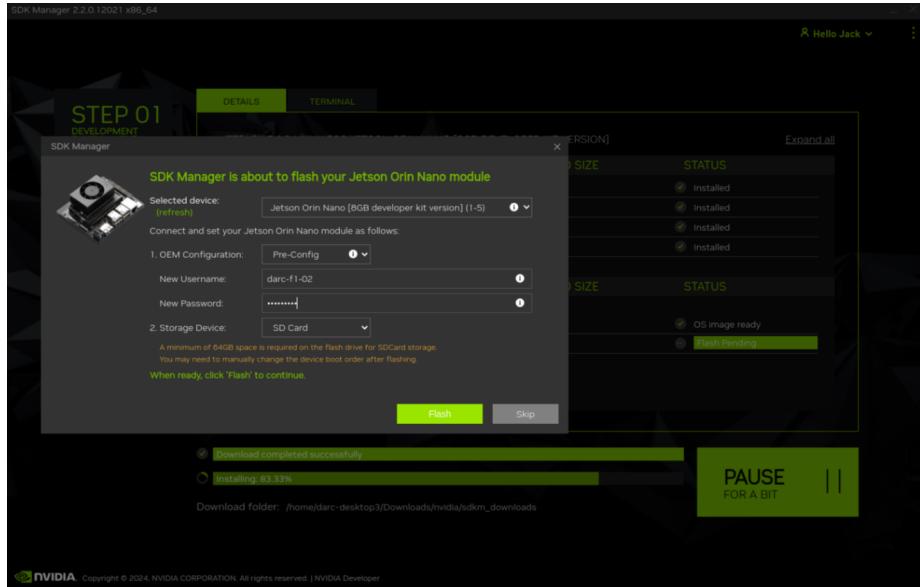

3. Before proceeding to step 3 **DISCONNECT** the jumper wire taking the Jetson out of force recovery mode. 4. It will state the specified folder doesn't exist.

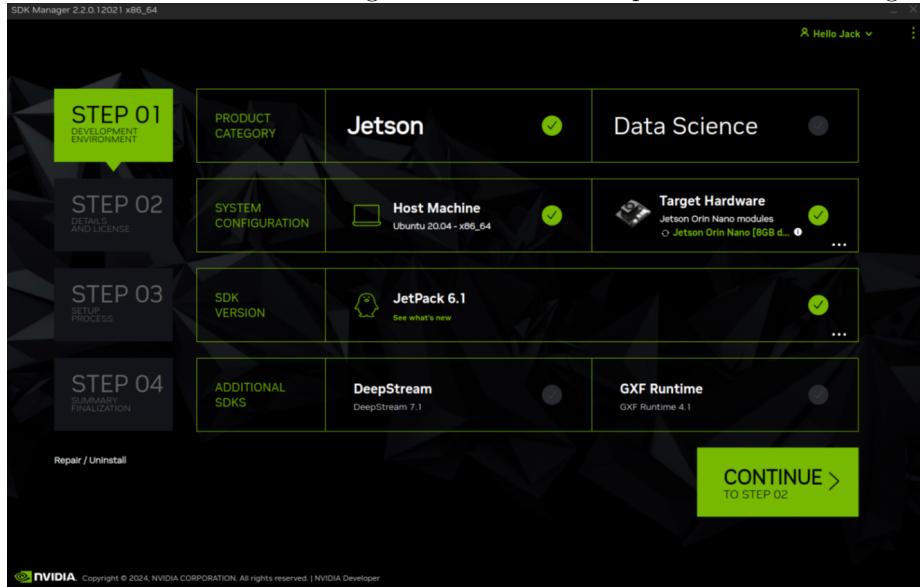

Click Create

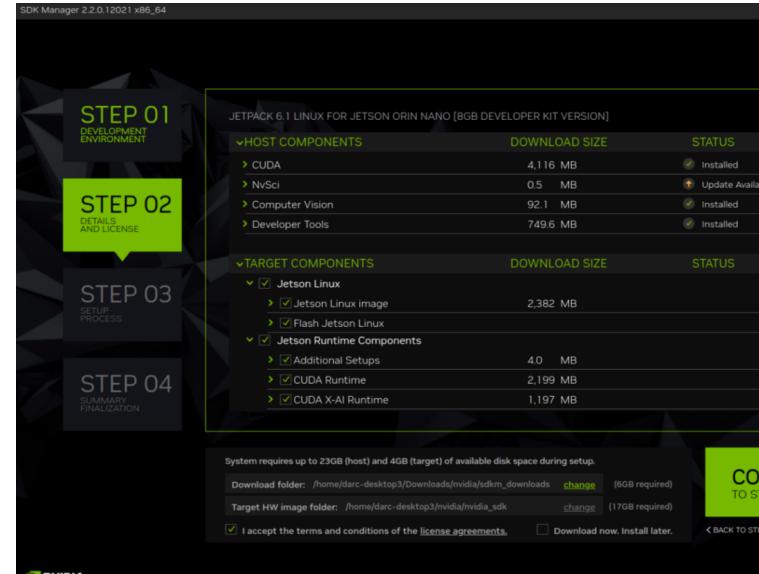

5. Next it will ask for your password.
- Then all of the host components will be installed and the Jetson Linux image will be created.
6. Once the OS image is ready the following screen will appear. Select the following parameters shown in the picture.

Once the parameters are selected click flash. ##### Flashing Jetpack 6.0 1. Select the following Parameters in Step 1 of SDK Manager.

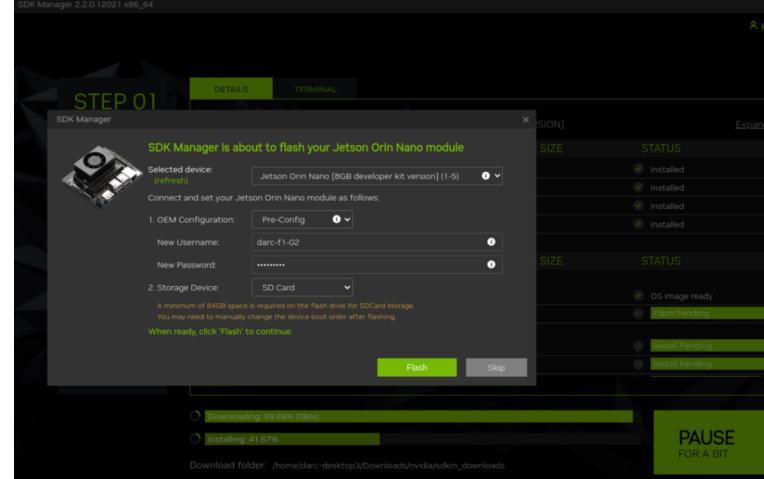

2. Continue to step 2 unsure that Jetson Linux and Jetson RUntime Components

- are selected under TARGET COMPONENTS.
- Before proceeding to step 3 **DISCONNECT** the jumper wire taking the Jetson out of force recovery mode.
  - It will state the specified folder doesn't exist. Click **Create**.
  - Next it will ask for your password.

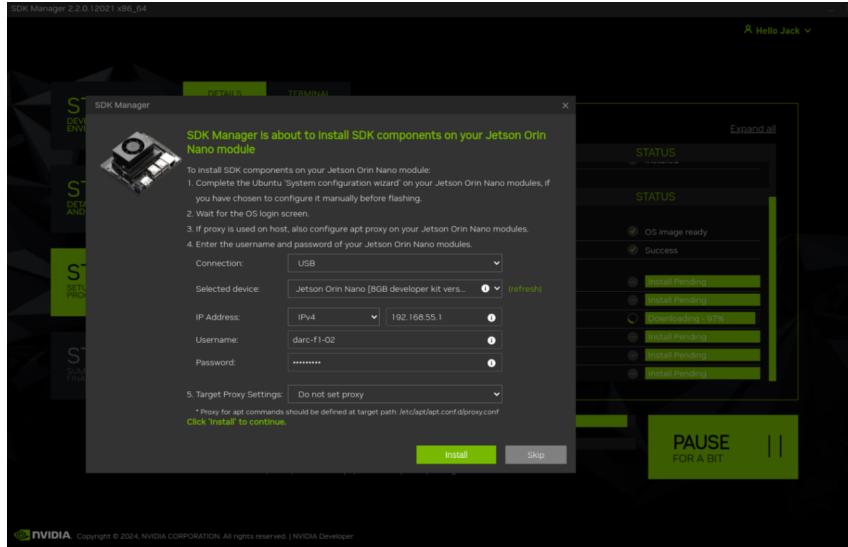

- Once the OS image is ready the following screen will appear. Select the fol-

lowing parameters shown in the picture. Then all of the host components will be installed and the Jetson Linux image will be created.

- Once the the flash finishes connect a monitor via display port, mouse and keyboard. The Jeston should be setup. Then login into the system, open

a terminal and type `ip addr show` confirm that the IP Address matches the IP address show on the Host computer. An example is shown below.

When this install is complete the Jetson is ready to proceed to the next step.

## 2. Run Jetson NX from SSD

In the build instruction we applied an SSD NVMe on to the Jetson NX. We will now make use of this SSD by switching the rootfs to point to the SSD. In effect, the system will now run from the SSD, the SD card is only there to boot the system. Therefore everything you install on your system will automatically installed on the SSD.

Please follow this tutorial here that has both video and commands integrated to enable your Jetson NX to run from the SSD

I highly recommend going to the “here” link above it is very helpful even though it is meant for the Jetson Xavier NX

### Important

These script changes the rootfs to the SSD after the kernel image is loaded from the eMMC/SD

The **here** link will take you to a site and execute the following steps

1. Ensure the SSD is correctly installed
2. Watch video on how to format SSD using this link
3. Open a terminal window on the Jetson and run the following commands

**Note :** You should do this process directly after creating a new SD card. On the JetsonHacks account on Github, there is a repository rootOnNVMe. Clone the

repository:

```
git clone https://github.com/jetsonhacks/rootOnNVMe
```

and switch over to that repository's directory:

```
cd rootOnNVMe
```

Next, copy the rootfs of the eMMC/SD card to the SSD

```
./copy-rootfs-ssd.sh
```

Finally, we will add a service which will run a script when the system starts up. The script will “pivot the root” to the SSD so that the system will run from the SSD.

```
./setup-service.sh
```

### 3. Configuring WiFi and SSH

#### Connect to Wifi

Go to top right corner and select network

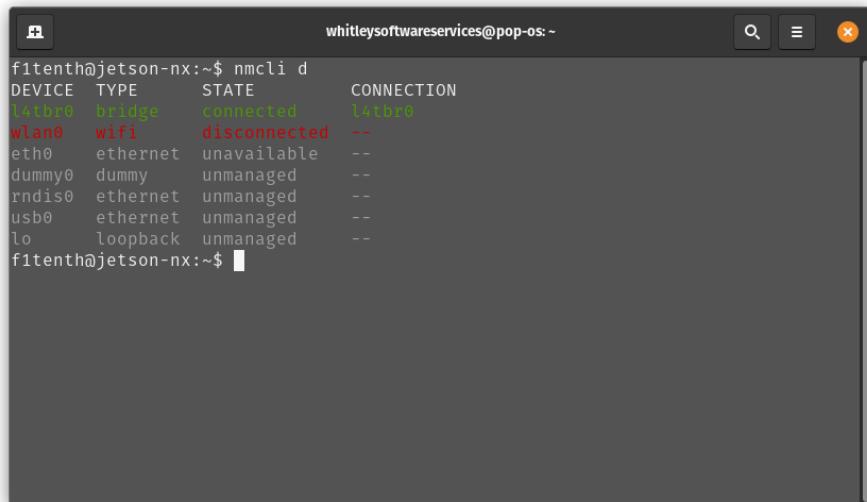

**Note:** If you are using Labnet you will need to add the MAC address to the Network. To find the MAC address use the command `ip link show`

Here is an example.

#### Configure SSH

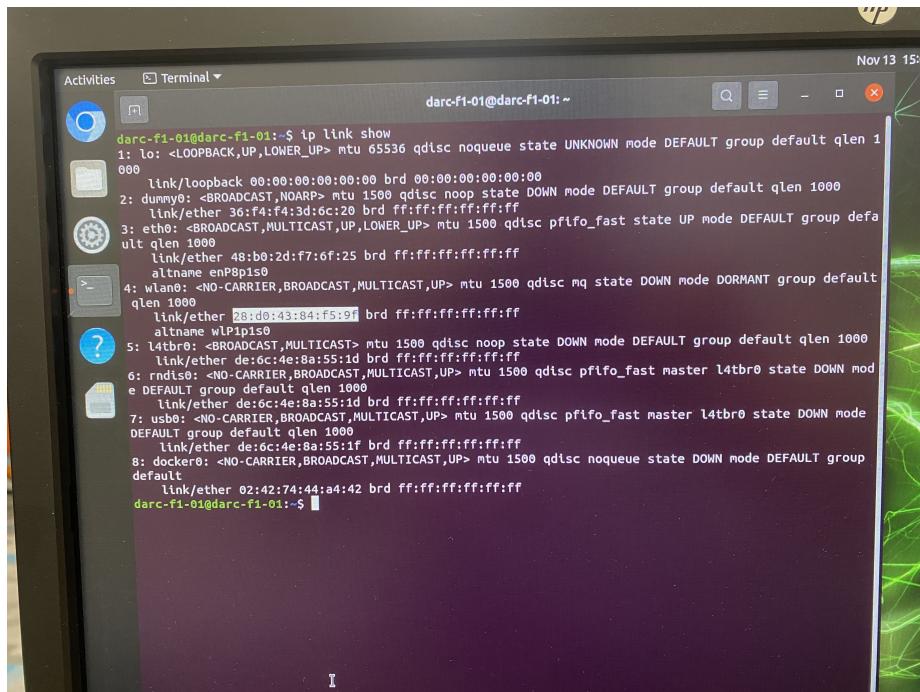

#### Setting static IP Address

Start by finding the wifi connection device. This can be done by running `nmcli d`

```
f1tenth@jetson-nx:~$ nmcli d
DEVICE  TYPE      STATE      CONNECTION
wlan0   wifi      disconnected  --
eth0    ethernet  unavailable --
dummy0  dummy     unmanaged   --
rndis0  ethernet  unmanaged   --
usb0   ethernet  unmanaged   --
lo     loopback  unmanaged   --
```

then use the device name for wifi.

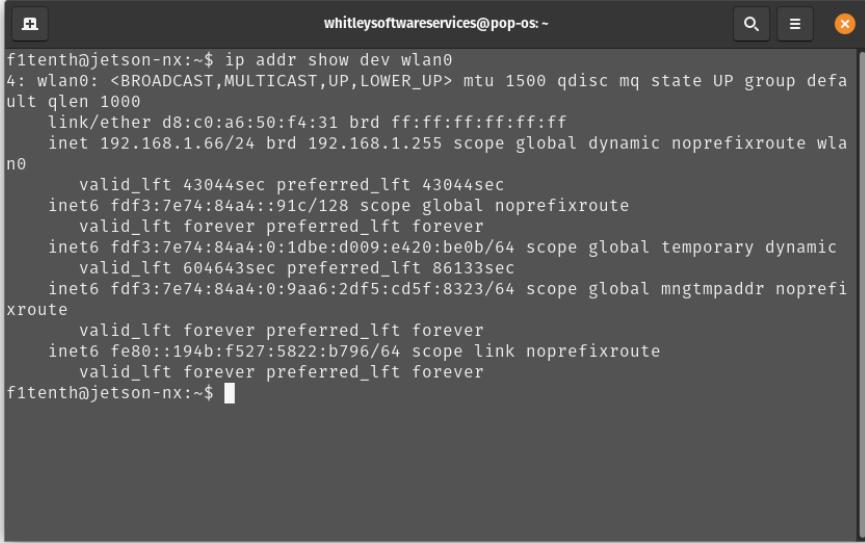

A screenshot of a Linux desktop environment showing a terminal window. The terminal window title is "Activities Terminal" and the date/time is "Nov 13 15:0". The terminal content displays the output of the command "ip link show". The output lists nine network interfaces (0: loopback, 1: dummy0, 2: eth0, 3: wlan0, 4: l1tbr0, 5: rndis0, 6: usbo, 7: l2tbr0, 8: docker0) with their respective details such as MTU, queueing discipline (qdisc), state, link layer address, and broadcast address.

```
darc-f1-01@darc-f1-01:~$ ip link show
1: lo: <LOOPBACK,UP,LOWER_UP> mtu 65536 qdisc noqueue state UNKNOWN mode DEFAULT group default qlen 1
    link/loopback 00:00:00:00:00:00 brd 00:00:00:00:00:00
2: dummy0: <BROADCAST,NOARP> mtu 1500 qdisc noop state DOWN mode DEFAULT group default qlen 1000
    link/ether 36:f4:f4:3d:6c:20 brd ff:ff:ff:ff:ff:ff
3: eth0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc pfifo_fast state UP mode DEFAULT group defa
ult qlen 1000
    link/ether 48:b0:2d:f7:6f:25 brd ff:ff:ff:ff:ff:ff
    altname enP8p1s0
4: wlan0: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc mq state DOWN mode DORMANT group default
qlen 1000
    link/ether 28:d0:43:84:f5:91 brd ff:ff:ff:ff:ff:ff
    altname wlP1p1s0
5: l1tbr0: <BROADCAST,MULTICAST> mtu 1500 qdisc noop state DOWN mode DEFAULT group default qlen 1000
    link/ether de:6c:4e:8a:55:1d brd ff:ff:ff:ff:ff:ff
6: rndis0: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc pfifo_fast master l4tbr0 state DOWN mode
DEFAULT group default qlen 1000
    link/ether de:6c:4e:8a:55:1d brd ff:ff:ff:ff:ff:ff
7: usbo: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc pfifo_fast master l4tbr0 state DOWN mode
DEFAULT group default qlen 1000
    link/ether de:6c:4e:8a:55:1f brd ff:ff:ff:ff:ff:ff
8: docker0: <NO-CARRIER,BROADCAST,MULTICAST,UP> mtu 1500 qdisc noqueue state DOWN mode DEFAULT group
default
    link/ether 02:42:74:44:a4:42 brd ff:ff:ff:ff:ff:ff
darc-f1-01@darc-f1-01:~$
```

Figure 8: alt text

For the example above the device name is wlan0

1. To get the currently-assigned IP address use the command `ip addr show dev wlan0`.

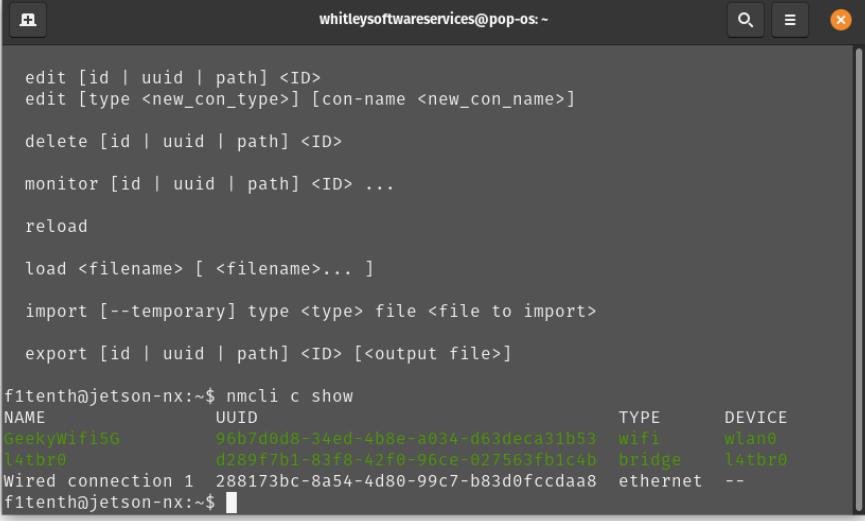

```
whitleysoftware@pop-os: ~
f1tenth@jetson-nx:~$ ip addr show dev wlan0
4: wlan0: <BROADCAST,MULTICAST,UP,LOWER_UP> mtu 1500 qdisc mq state UP group default qlen 1000
    link/ether d8:c0:a6:50:f4:31 brd ff:ff:ff:ff:ff:ff
        inet 192.168.1.66/24 brd 192.168.1.255 scope global dynamic noprefixroute wlan0
            valid_lft 43044sec preferred_lft 43044sec
            inet6 fdf3:7e74:84a4::91c/128 scope global noprefixroute
                valid_lft forever preferred_lft forever
            inet6 fdf3:7e74:84a4:0:1dbe:d009:e420:be0b/64 scope global temporary dynamic
                valid_lft 604643sec preferred_lft 86133sec
            inet6 fdf3:7e74:84a4:0:9aa6:2df5:cd5f:8323/64 scope global mngtmpaddr noprefixroute
                valid_lft forever preferred_lft forever
            inet6 fe80::194b:f527:5822:b796/64 scope link noprefixroute
                valid_lft forever preferred_lft forever
f1tenth@jetson-nx:~$
```

Currently-connected WiFi IP address.¶

2. To set a static IP address, you will also need to know the name of the connection. This is usually the same as the SSID of the WiFi network but not always. To see the list of current connections, use the command `nmcli c show`.

List of connections.¶

3. To set a static IP address use the command `sudo nmcli c mod [CONNECTION_NAME] ipv4.address [NEW_ADDRESS]/[CIDR]` where [CONNECTION\_NAME] is replaced with the name of your WiFi connection that you got from step 8, [NEW\_ADDRESS] is replaced with the static IP address that you want to set, and [CIDR] is the CIDR representation of the subnet (usually 24).

```
whitleysoftwareservices@pop-os:~
```

```
edit [id | uuid | path] <ID>
edit [type <new_con_type>] [con-name <new_con_name>]

Wired connection 1  288173bc-8a54-4d80-99c7-b83d0fcddaa8  ethernet  --
f1tenth@jetson-nx:~$ nmcli c mod GeekyWifi5G ipv4.address 192.168.1.202/24
Error: Failed to modify connection 'GeekyWifi5G': Insufficient privileges.
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.address 192.168.1.202/24
[sudo] password for f1tenth:
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.gateway 192.168.1.1
```

#### Setting IP gateway.¶

5. To set the connection's DNS servers, use the command `sudo nmcli c mod [CONNECTION_NAME] ipv4.dns "[DNS_SERVER1]"` where `[CONNECTION_NAME]` is replaced with the name of your WiFi connection that you got from step 8 and `[DNS_SERVERS]` is replaced with a comma-separated list of DNS server IP addresses. Google DNS servers at 8.8.8.8 and 8.8.4.4 are recommended.
6. To disable DHCP and always use the static IP address on this connection, use the command `sudo nmcli c mod [CONNECTION_NAME] ipv4.method manual` where `[CONNECTION_NAME]` is replaced with the name of your WiFi connection that you got from step 8.

```

whitleysoftwareservices@pop-os: ~
reload
load <filename> [ <filename>... ]
import [--temporary] type <type> file <file to import>
export [id | uuid | path] <ID> [<output file>]

f1tenth@jetson-nx:~$ nmcli c show
NAME           UUID                                  TYPE      DEVICE
GeekyWifi5G    96b709d8-34ed-4b8e-a034-d63deca31b53  wifi      wlan0
l4tbr0         d289f7b1-83f8-42f0-96ce-027563fb1c4b  bridge    l4tbr0
Wired connection 1  288173bc-8a54-4d80-99c7-b83d0fccdaa8  ethernet --
f1tenth@jetson-nx:~$ nmcli c mod GeekyWifi5G ipv4.address 192.168.1.202/24
Error: Failed to modify connection 'GeekyWifi5G': Insufficient privileges.
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.address 192.168.1.202/24
[sudo] password for f1tenth:
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.gateway 192.168.1.1
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.dns "8.8.8.8, 8.8.4.4"
f1tenth@jetson-nx:~$ sudo nmcli c mod GeekyWifi5G ipv4.method manual
f1tenth@jetson-nx:~$ 

```

Setting connection to always use static IP.¶

7. To save the changes you've made, run the command `sudo nmcli c up [CONNECTION_NAME]` where [CONNECTION\_NAME] is replaced with the name of your WiFi connection that you got from step 8.
8. To verify that you can SSH into the NVIDIA Jetson Orin Nano Developer Kit, verify that the Pit/Host PC is connected to the same network as the Jetson Orin Nano Developer Kit and use an SSH client on the Host PC to connect to the new IP address of the Developer Kit. On Linux this would be done with the command `ssh f1tenth@[IP_ADDRESS]` where [IP\_ADDRESS] is replaced with the static IP address that you assigned to the Developer Kit. After you have verified that SSH works correctly, you can close the connection to the Developer Kit in your terminal emulator.

**After setup SSH using following command**

```

ssh -p 22 User@ip adress
example: ssh -p 22 darc-f1@10.152.69.100

```

**Note:** If network is having difficulty connecting go to the wi-fi settings under the IPv4 tab and select Automatic unsure the DNS is clear.

#### 4. Updating Packages

All further steps assume that your NVIDIA Jetson Orin Nano Developer Kit is connected to the internet. You can execute all the commands directly in the terminal application of the NVIDIA Jetson. Now we are updating the Ubuntu system on the Jetson NX.

1. To update the list of available packages, run `sudo apt update`.

2. To install all available updates, run `sudo apt full-upgrade`.
3. Once all packages have been upgraded run `sudo reboot` to restart the Developer Kit and apply any changes.

## 5. Setup Bluetooth and Connect Controller

**- Steps to Setup Bluetooth on Jetson Orin Nano:** Update System Packages: Make sure the system is up to date.

```
sudo apt update
sudo apt upgrade
```

**- Install Bluetooth Packages:** Install the necessary Bluetooth packages if they're not already installed.

```
sudo apt install bluez bluez-tools
sudo apt install pulseaudio pulseaudio-module-bluetooth
```

**- Enable Bluetooth Service:** Start and enable the Bluetooth service.

```
sudo systemctl start bluetooth
sudo systemctl enable bluetooth
```

If your adapter is detected, you should see output like hci0: Type: BR/EDR .... If no device is found, it might be due to a missing driver or unsupported hardware.

**Check if bluez and bluez-tools are installed:** Run this command:

```
sudo dpkg -l | grep bluez
```

**If the packages are installed, you should see an output like this:**

```
ii  bluez          <version>      <architecture>  <description>
ii  bluez-tools    <version>      <architecture>  <description>
```

Run this command:

```
dpkg -l | grep pulseaudio
```

This will show all pulseaudio related packages that are installed. Look for `pulseaudio` and `pulseaudio-module-bluetooth` in the output. If installed, the output will look similar to:

```
ii  pulseaudio        <version>      <architecture>  <description>
ii  pulseaudio-module-bluetooth <version>      <architecture>  <description>
```

If they are not installed, there will be no output or only partial results.

**Now you should be able to go to settings and connect the controller**

## 6. Creating a Swapfile

1. Run the following commands to create a swapfile which can help with memory-intensive tasks

```
sudo fallocate -l 4G /var/swapfile
sudo chmod 600 /var/swapfile
sudo mkswap /var/swapfile
sudo swapon /var/swapfile
sudo bash -c 'echo "/var/swapfile swap swap defaults 0 0" >> /etc/fstab'
```

## 2. Connecting the Pit/Host and the Jetson Orin Nano

### Overview

We could now log into the Jetson using a monitor, keyboard, and mouse, but ideally we would want remote access when we're driving the car. Throughout this tutorial, you will be asked to configure the Jetson's and your laptop's network settings. Make sure to get these right! Using the wrong IP address may lead to conflicts with another classmate, meaning neither of you will be able to connect.

If your **Pit/Host** computer has WiFi capability, you connect both the computer and the F1TENTH car to a wireless router which reserves a static IP address for Jetson Orin Nano on the vehicle.

If the **Pit/Host** computer doesn't have Wifi capability:

1. Connect the Pit/Host computer to a WiFi router via an ethernet cable.
2. Connect the NVIDIA Jetson NX to the same router via Wifi.

To make this section easy to follow, the Routers WiFi network SSID will be called and referred to **F1TENTH\_WIFI**. In your scenario, it'll be the SSID of your router's access point.

### 1. Vehicle Hardware Setup

If you have a NVIDIA Jetson Orin Nano, it comes with a network card onboard. Make sure the antennas are connected. The battery should be plugged into the vehicle and the Powerboard should be on.

### 2. Connecting the NVIDIA Jetson NX to WiFi

Power up the F1TENTH vehicle and connect the car to a monitor (via HDMI) and both a mouse and keyboard (via USB). You see the Jetson Orin Nano is showing its main Desktop which is an UBUNTU 22.04 version. You can now connect the NVIDIA Jetson Nano to the Labnet by clicking on wireless

icon on top-right corner of Ubuntu Desktop and selecting Labnet. It might take a while for the NVIDIA Jetson Orin Nano to discover the wireless network.

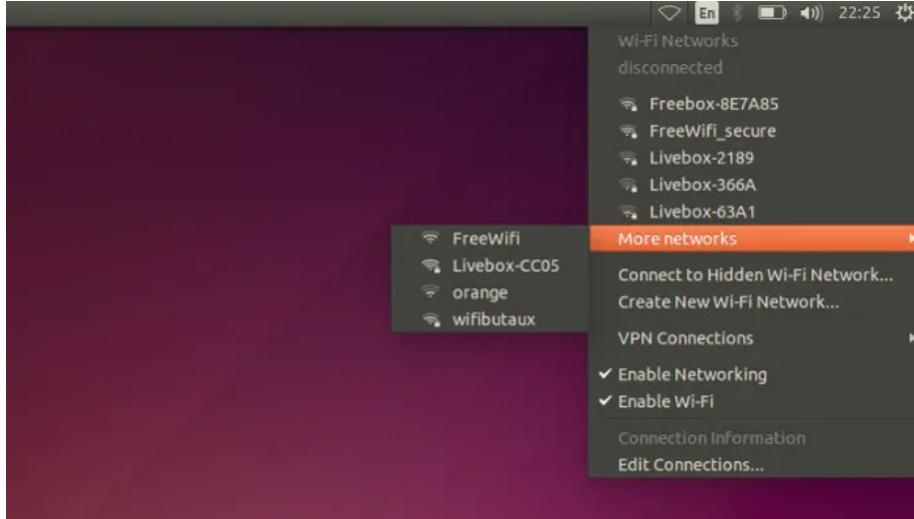

Figure 10: alt text

After you're connected to the wireless network, open a terminal and type:

You should see something similar to this:

```
eth0: flags=4099<UP,BROADCAST,MULTICAST> mtu 1500 ether  
00:04:4b:cb:d9:52 txqueuelen 1000 (Ethernet) RX packets 0 bytes 0 (0.0 B) RX

carrier 0 collisions 0 NoMachine Ctrl+alt+d'
```

You should be able to find your car's assigned IP address under `wlan0`, then after inet

#### ## 3. Connecting the Pit/Host Computer to WiFi

Now, on the Pit/Host laptop, connect to the same wireless network, `Labnet` and find its

If you're running Linux on the Pit laptop in a virtual machine (VM), connect the Pit computer

#### ## 4. Connecting to the Pit/Host to the NVIDIA Jetson NX

Now that the car and the laptop are on the same network, you should check that you can ping

On the NVIDIA Jetson NX, open a terminal and type: `ping 192.168.1.151` (This is the IP  
On the Pit computer, open a terminal and type `ping 195.0.0.5` (This is the IP address of the car).  
Remember to replace the IP addresses in the two lines above with your specific addresses.

You can now SSH into your car from your laptop. Use `ssh` in the terminal if you're on [macOS]

\*\*An example of this ssh command is as follows - `ssh -p 22 darc-f1-01@10.152.69.216`\*\*

We recommend using [tmux] (<https://www.hamvoeke.com/blog/a-quick-and-easy-guide-to-tmux/>) while

#### <!-- # 5. Using a Remote Desktop

### I am not currently using the remote desktop I am only utilizing ssh for Host Machine

Although we now have SSH access to the car, it is still inconvenient to run GUI applications

First, download NoMachine for your \*\*pit/host\*\* computer's specific OS [here] (<https://www.nomachine.com/>)

After NoMachine is installed on both sides, go to your pit/host's NoMachine, click \*\*Add\*\* to

#### A. Install [NoMachine] (<https://www.nomachine.com/download>) on Host/Pit computer  
#### B. Download and install NoMachine on Jetson with the following commands  
`wget https://www.nomachine.com/free/arm/v8/deb -O nomachine.deb`

`sudo dpkg -i nomachine.deb`

#### C. Setup GNOME Flashback instead of XFCE using NoMachine

Run the following code in terminal

```
```sudo apt install gnome-session```
```sudo systemctl set-default multi-user.target```
```sudo gedit /usr/NX/etc/node.cfg````
```

Replace the following DefaultDesktopCommand with ```DefaultDesktopCommand "/usr/bin/gnome-se

Run the following line in the terminal

```
```sudo /usr/NX/bin/nxserver --restart````
```

```
```sudo reboot```
-->
```

# Install F1TENTH Driver Stack

**\*\*Note\*\* -**

This section assumes that you have already completed Building the Car and System Configuration.

At the end of this section, you will have the VESC tuned and the lidar connection completed.

**\*\*Difficulty Level\*\*:** Intermediate-Advanced

**\*\*Approximate Time Investment\*\*:** 1.5 hour

With the physical car is built and the system configuration setup, we can start to install the

## 1. Configuring the VESC

#### Important Safety Tips

Put your car on an elevated stand so that its wheels can turn without it going anywhere. If

Make sure you hold on to the car while testing the motor to prevent it from flying off the stand.

Make sure there are no objects (or people) in the vicinity of the wheels while testing.

Use a fully-charged LiPO battery instead of a power supply to ensure the motor has enough current.

### 1. Installing the VESC Tool

We need to configure the VESC so that it works with our motor and vehicle transmission. Before

### 2. Powering the VESC

First we need to power the VESC. Plug the battery in, and make sure the polarity is correct.

! [alt text] (<Pictures/F1tenth Build/vesc01.jpeg>)

Next, unplug the USB cable of the VESC from the Jetson NX and plug the USB into your laptop

![alt text](<Pictures/F1tenths Build/vesc02.jpeg)

### 3. Connecting the VESC to Your Laptop  
Launch the VESC Tool. On the Welcome page, press the AutoConnect button on bottom left of the screen.

![alt text](image-6.png)  
Use AutoConnect

### 4. Updating the Firmware on the VESC  
The first thing you'll need to do is to update the firmware onboard the VESC. Depending on the VESC version, you may need to use the latest default firmware or a custom one.

With VESC Tool versions released after Mar. 31 2021, you can use the latest default firmware.

![alt text](<Screenshot from 2025-01-15 16-10-15.png>)

### 5. Uploading the Motor Configuration XML  
After firmware update, Select Load Motor Configuration XML from the drop down menu and select the XML file.

![alt text](<Pictures/F1tenths Build/xml.webp>)

### 6. Detecting and Calculating Motor Parameters  
To detect and calculate the FOC motor parameters, navigate to the FOC tab under Motor Settings.

![alt text](<Pictures/F1tenths Build/detect\_motor.webp>)

After the motor parameters are measured, the fields at the bottom of the screen should turn green.

![alt text](<Pictures/F1tenths Build/apply\_motor.png>)

### 7. Changing the Openloop Hysteresis and Openloop Time  
Navigate to the \*\*Sensorless\*\* tab on top of the screen. Change the \*\*Openloop Hysteresis\*\* and \*\*Openloop Time\*\*.

![alt text](<Pictures/F1tenths Build/open\_loop.webp>)

### 8. Tuning the PID controller  
Now you can start tuning the speed PID controller. To see the RPM response from the motor, navigate to the Realtime tab.

![alt text](<Pictures/F1tenths Build/realtimewebp>)

To create a step response for the motor, you can set a target RPM at the bottom of the screen.

![alt text](<Pictures/F1tenths Build/response.webp>)

You want to look for a clean step response that has a quick rise time and zero to very little overshoot.

! [alt text] (<Pictures/F1tenths Build/pid\_gains.webp>)

These are my settings.

! [alt text] (<Screenshot from 2024-10-07 17-57-01.png>)

### 9. Changing the hardware speed limit

By default, the motor configuration sets a safe top motor RPM. If you wish to change the han-

! [alt text] (<Pictures/F1tenths Build/erpm.webp>)

**\*\*Danger\*\***

Please see the Odometry Tuning section in the software stack setup to see how vehicle velocity is converted to ERPM for the motor to calculate a safe maximum erpm for your motor.

## 2. Hokuyo 10LX Ethernet

**\*\*Note\*\***

If you have a 30LX or a LIDAR that connects via USB, you can skip this section.

**\*\*Approximate Time Investment:\*\*** 30 minutes

Connect to the Jetson NX either via SSH or a wired connection (monitor, keyboard, mouse).

In order to utilize the 10LX you must first configure the eth0 network. From the factory the

Open Network Configuration in the Linux GUI on the Jetson Orin Nano. In the ipv4 tab, add a

IP address ` ``192.168.0.15`` ``

Subnet mask is ` ``255.255.255.0`` ``

Gateway is ` ``192.168.0.10`` ``

Call the connection Hokuyo. Save the connection and close the network configuration GUI.

When you plug in the 10LX make sure that the Hokuyo connection is selected. If everything is

If this doesn't work use the following commands

Open the terminal

```
sudo ip addr add 192.168.0.1/24 dev eth0
```

Then go to setting and edit the eth0 connection. By going to the ipv4 tab and entering in the

Now try to ping `192.168.0.10`.

### ## 3. F1TENTH Driver Stack Setup

\*\*NOTE: This is how to setup the driver stack WITHOUT DOCKER\*\*

\*\*Approximate Time Investment:\*\* 1.5 hour

#### ### Overview

This setup is being ran on JetPack 6.0 since the Jetson can run on Ubuntu 22.04, and we can

In the following section, we'll go over how to set up the drivers for sensors and the motor

#### A. Setting up udev rules for our sensors.

#### B. Installing ROS 2 and its utilities.

#### C. Setting up the driver stack.

#### D. Launch teleoperation and the LiDAR.

Everything in this section is done on the \*\*Jetson Orin Nano Dev Kit\*\* so you will need to

#### ## A. udev Rules Setup

\*Goal is to name the VESC and the Hokuyo Lidar (Ethernet connection)

### Naming the Lidar Sensor

```
`sudo gedit /etc/udev/rules.d/99-ethernet-hokuyo.rules`
```

```
SUBSYSTEM=="net", ACTION=="add", ATTR{address}=="48:b0:2d:eb:e4:dd", NAME="hokuyo"
```

### Naming the VESC

```
sudo gedit /etc/udev/rules.d/99-vesc.rules`
```

```
KERNEL=="ttyACM[0-9]*", ACTION=="add", ATTRS{idVendor}=="0483", ATTRS{idProduct}=="5740",
```

```
Finally, trigger (activate) the rules by running  
sudo udevadm control -reload-rules sudo udevadm trigger  
Reboot your system, and you should find VESC by running `ls /dev/sensors`.
```

## ## B. Installing ROS 2 and its Utilities

Below are instructions on how to install ROS 2 humble and the necessary utilities.

### ### Set locale

Make sure you have a locale which supports UTF-8. If you are in a minimal environment (such as locale #) check for UTF-8

```
sudo apt update && sudo apt install locales sudo locale-gen en_US en_US.UTF-  
8 sudo update-locale LC_ALL=en_US.UTF-8 LANG=en_US.UTF-8 export  
LANG=en_US.UTF-8
```

locale # verify settings

### ### Setup Sources

You will need to add the ROS 2 apt repository to your system.

First ensure that the Ubuntu Universe repository is enabled.

```
sudo apt install software-properties-common sudo add-apt-repository universe
```

Now add the ROS 2 GPG key with apt.

```
sudo apt update && sudo apt install curl -y sudo curl -sSL https://raw.githubusercontent.com/ros/rosdistro/master/ros2.gpg -o /usr/share/keyrings/ros-archive-keyring.gpg
```

Then add the repository to your sources.list.

```
echo "deb [arch=$(dpkg --print-architecture) signed-by=/usr/share/keyrings/ros-  
archive-keyring.gpg] http://packages.ros.org/ros2/ubuntu $(. /etc/os-release &&  
echo $UBUNTU_CODENAME) main" | sudo tee /etc/apt/sources.list.d/ros2.list  
> /dev/null
```

### ### Install ROS 2 packages

Update your apt repository caches after setting up the repositories.

```
sudo apt update
```

ROS 2 packages are built on frequently updated Ubuntu systems. It is always recommended that

```
sudo apt upgrade
```

```
<span style="color:yellow;">
```

### ### Warning

Due to early updates in Ubuntu 22.04 it is important that `systemd` and `udev`-related packages are correctly installed. Please refer to [ros2/ros2#1272](#) and Launchpad #1974196 for more information.

```
<span style="color:white;">

Desktop Install (Recommended): ROS, RViz, demos, tutorials.
sudo apt install ros-humble-desktop
### Try an Example to see if it works

In one terminal, source the setup file and then run a C++ talker:
source /opt/ros/humble/setup.bash ros2 run demo_nodes_cpp talker
In another terminal source the setup file and then run a Python listener:
source /opt/ros/humble/setup.bash ros2 run demo_nodes_py listener
You should see the `talker` saying that it's `Publishing` messages and the `listener` saying

### Now install ROS Utilities

### Install Colcon
sudo apt install python3-colcon-common-extensions
### Install dependencies
sudo apt install python3-bloom python3-rosdep fakeroot debhelper dh-python
### Initialize rosdep

Initialize the rosdep database by calling:
sudo rosdep init rosdep update
Note that the `rosdep init` command may fail if it has already been initialized in the past.

## D. Setting up the driver stack
First, we'll create a ROS 2 workspace for our driver stack with the following commands. We'll
cd $HOME mkdir -p fltenths_ws/src
Then, make this into a ROS 2 workspace by running:
cd fltenths_ws colcon build
Next, we'll clone the repo into the src directory of our workspace:
cd src git clone https://github.com/fltenths/fltenths_system.git
```

Then use the following commands to use the humble-devel branch from the Fitenth repo

```
cd fitenth_system git checkout humble-devel
```

Then we'll update the git submodules and pull in all the necessary packages

```
git submodule update --init --force --remote
```

After git finishes cloning, we can now install all dependencies for our packages with rosdep

```
cd $HOME/fitenth_ws source /opt/ros/humble/setup.bash rosdep update rosdep install --from-paths src -i -y
```

Lastly, after dependencies are installed, we can build our workspace again with the driver workspace

```
colcon build
```

You can find more details on how the drivers are set up in the README of the fitenth\_system workspace.

Install colcon If you haven't installed colcon yet, follow these steps:

```
### Error
```

If the following error occurs

CMake Error at /opt/ros/humble/share/io\_context/cmake/io\_context-extras.cmake:17 (find\_package): By not providing "Findasio\_cmake\_module.cmake" in CMAKE\_MODULE\_PATH this project has asked CMake to find a package configuration file provided by "asio\_cmake\_module", but CMake did not find one.

Could not find a package configuration file provided by "asio\_cmake\_module" with any of the following names:

```
asio_cmake_moduleConfig.cmake
asio_cmake_module-config.cmake
```

Add the installation prefix of "asio\_cmake\_module" to CMAKE\_PREFIX\_PATH or set "asio\_cmake\_module\_DIR" to a directory containing one of the above files. If "asio\_cmake\_module" provides a separate development package or SDK, be sure it has been installed. Call Stack (most recent call first):

```
/opt/ros/humble/share/io_context/cmake/io_contextConfig.cmake:41 (include)
/opt/ros/humble/share/serial_driver/cmake/ament_cmake_export_dependencies-extras.cmake:21 (find_package) /opt/ros/humble/share/serial_driver/cmake/serial_driverConfig.cmake:41 (include) /opt/ros/humble/share/ament_cmake_auto/cmake/ament_auto_find_build_dependencies.cmake:67 (find_package) CMakeLists.txt:14 (ament_auto_find_build_dependencies)
```

Use the following code

```
sudo apt update sudo apt install ros-humble-asio-cmake-module
```

\*\*There will be several warnings please use the following commands to mitigate these warnings

```
Code format: `find . -type f -exec sed -i 's/old/new/g' {} \;`
```

```

find . -type f -exec sed -i 's/script-dir/script_dir/g' {} ; find . -type f -exec sed
-i 's/install-script/install_script/g' {}

## E. Launch teleoperation and the LiDAR

This section assumes that the lidar has already been plugged in (either to the USB hub or to

Before the bringup launch, you'll have to set the correct parameters according to which LiDAR
$HOME/fltenths_ws/src/fltenths_system/fltenths_stack/config/

If you're using an ethernet based LiDAR, set the ip_address field to the corresponding ip address

If you're using a USB based LiDAR, comment out the ip_address field, and uncomment the line

In your running container, run the following commands to source the ROS 2 underlay and our workspace
source /opt/ros/humble/setup.bash cd $HOME/fltenths_ws source install/setup.bash

Then, you can launch the bringup with:
ros2 launch fltenths_stack bringup_launch.py

Running the bringup launch will start the VESC drivers, the LiDAR drivers, the joystick driver, and
source /opt/ros/humble/setup.bash cd $HOME/fltenths_ws source install/setup.bash rviz2

Change the **Fixed Frame** parameter from **map** to **laser**
The rviz window should show up. Then you can add a LaserScan visualization in rviz on the /sensors topic

If RViz2 is populating a blank screen it could be because RViz2 is misconfigured. Try the following steps:
1. Close RViz2
2. Delete the saved configuration file (if it exists):
rm ~/rviz2/default.rviz
3. Relaunch RViz2:
rviz2

# Test controller

connect the controller using bluetooth from the settings
sudo apt install jstest-gtk

Then run `jstest-gtk` to open the tester and by selecting the 3 wireless controller

```

! [alt text] (image-7.png)

# Manual Test of Teleop Commands

If you confirm that joystick inputs are present but the car isn't responding, you can try pu

```
ros2 topic pub /ackermann_cmd ackermann_msgs/msg/AckermannDriveStamped  
"drive: {speed: 1.0, steering_angle: 0.0}"
```

# Driving the F1Tenth Car

## Manual Driving

### Overview

Before we can get the car to drive itself, it's a good idea to test the car to make sure it

You \*\*MUST\*\* connect to the Jetson via SSH or Remote Desktop for this section.

### 1. Vehicle Inspection

We want to minimize the number of accidents so before we begin, let's first inspect our vehicle.

1. Make sure you have the car running off its LIPO battery.

2. Plug the USB dongle receiver of the Logitech Joypad into the USB hub.

3. Make sure you have the VESC connected.

4. Ensure that both your car and laptop are connected to a wireless access point if you need to.

5. Make sure you've cloned the f110\_system repository and set up your docker container as explained in the previous section.

6. This section uses the program tmux (available via apt-get) to let you run multiple terminals simultaneously.

### 2. Driving the Car

1. Open a terminal on the Pit laptop and SSH into the car from your computer.

2. Launch teleop following the instructions for Launching and Testing teleop and the LiDAR interface.

3. Hold the LB button (Dead man's switch) on the controller to start controlling the car. Use the arrow keys to move the car.

### Troubleshooting

During teleop, if the joystick is not mapped correctly, you can change the mapping in `/f1tenth/teleop` configuration file.

If \*\*nothing happens\*\*, one reason can be that the driver name is listening on the wrong port.

Note that the \*\*LB button acts as a "dead man's switch"\*\*, as releasing it will stop the car.

You can see a **mapping of all controls** used by the car in the `joy\_teleop.yaml` file. For example:

- Motor rotation direction negated**: If your car is driving backwards when commanded driving forward.
- VESC out of sync errors**: Check that the VESC is connected. If the error persists, make sure the connection is stable.
- Serial port busy errors**: Your VESC might have just booted up, give it a few seconds and try again.
- SerialException errors**: and you're using the 30LX Hokuyo, the errors might be due to a problem with the serial connection or the sensor itself.
- urg\_node related errors**: Check the ports (e.g. an ip address in sensors.yaml) can only be used once.

## Now is the Time to setup NoMachine

## Calibrating the Odometry

### Calibrating the steering and odometry

Now that everything is built, configured, and installed, the odometry of the vehicle needs to be calibrated.

1. The parameters in vesc.yaml need to be calibrated. This yaml file is located at:  
`HOME/f1tenth_ws/src/f1tenth_system/f1tenth_stack/config/vesc.yaml`  
 if you're using the driver stack natively, or on the host if you're using docker containers.  
`$/f1tenth_ws/src/f1tenth_system/f1tenth_stack/config/vesc.yaml`  
 in the container if you're using docker containers. Note that the config directory has all the files needed for calibration.
2. In the first few steps, make sure you've lifted the car up with a pit stand or a box, so the wheels don't touch the ground.
3. First, we need to check if our motor is rotating in the right direction. If when given a positive speed, the motor rotates in the wrong direction, we need to flip the polarity.
4. Next, we'll also need to check if the vesc driver is interpreting the motor rotation direction correctly. This involves modifying the code in `vesc_to_odom.cpp`.  
`$HOME/f1tenth_ws/src/f1tenth_system/vesc/vesc_ackermann/src/vesc_to_odom.cpp`  
 if you're using the driver stack natively, or on the host if you're using docker containers.  
`/f1tenth_ws/src/f1tenth_system/vesc/vesc_ackermann/src/vesc_to_odom.cpp`  
 in the container if you're using docker containers.

Modify line `100` so it reads:

```
double current_speed = -(state->state.speed - speed_to_erm_offset_) / speed_to_erm_gain_;
```

After changing the source code, you'll have to go back to the workspace at /f1tenths\_ws, and call colcon build again. Also remember that whenever you rebuild the workspace, you'll have to call the commands to source the underlay and the overlay again.

### Note

**In the following steps that adjust parameters in the yaml file, you'll have to call colcon build after every change before launching teleop again.**

5. After the motor directions are fixed, and the odometry is in the right direction, we can now start tuning the steering and the odometry gains. The first to be tuned is the Steering Offset. This parameter will determine the offset we put on the servo, and whether the car can drive straight when given no steering input. Again, start teleop with the bringup launch. Drive the car in a straight line a couple times with no steering input for a couple meters, and see if it's driving straight. Adjust the steering\_angle\_to\_servo\_offset parameter in vesc.yaml if it's not. Make small adjustment everytime (in the magnitude of 0.1). Repeat until you find the correct offset so the car drives straight.

### Note

In the following steps, you'll need to lay down the tape measure straight on the ground. It is helpful to tape the tape measure so it doesn't move around.

Next, we'll tune the Steering Gain. This parameter determines the smallest turning radius of the car. We'll determine the desired turning radius given the maximum steering angle of the car we're setting, which is 0.36 radians in both directions. The corresponding turning radius could be then calculated with  $R = L/(2 \sin(\beta))$ , where  $L$  is the wheelbase of the car, which is around 0.33 meters;  $\beta$  is calculated as  $\arctan(0.5 \tan(\delta))$ , with  $\delta$  being the maximum steering angle of the car. After calculations, when turning a half circle, the desired diameter of the half circle should be 1.784 meters.

Place the car at the 0 of the tape measure such that the rear axle of the car is parallel to the tape measure, and the x-axis (roll axis) of the car coincides with the tape measure at 0.

Start teleop. Set the steering angle to the maximum to one side depending on your setup (e.g. if the rest of the tape measure is on the left side of the car, turn left).

Hold the steering, and drive forward slowly and steadily until the car runs over the tape measure again and the rear axle realigns with the tape measure. Now the car should be in the opposite direction to where you started.

Take a measurement on the tape measure. The goal is 1.784 meters. If the measurement overshoots, increase the gain slightly (0.1 at a time). If it undershoots,

decrease the gain. Repeat the process until you've hit 1.784 meters.

If you notice that the wheels turn to different angles on the two directions when give maximum steering angles, adjust the servo\_min and servo\_max numbers until they're symmetric.

Next, we'll tune the ERPM gain. This parameter determines the conversion from desired velocity in meters/second to desired motor ERPM.

Place the car at the 0 of the tape measure such that the rear axle of the car coincides with 0 and the x-axis (roll axis) of the car is parallel to the tape measure.

Start teleop. Open another bash window in the container, and run ros2 topic echo -no-arr /odom. We're particularly interested in the pose/pose/position/x value. Before giving any driving commands on the joystick, this value should be zero. If it is not zero, kill teleop and restart teleop.

If you notice this value is drifting even when the car is stationary. Change the speed\_to\_erp\_offset value so that it stops drifting.

Drive slowly and steadily forward without any steering input for more than 3 meters. Record the distance traveled by the car on the tape measure. Note that you'll have to take the reading from the rear axle.

Compare the measured value to the value shown in the echoed message. If the distance reported by echo is larger, decrease the speed\_to\_erp\_gain value. Otherwise increase the gain. The change is usually on the order of thousands. Note that changing this value also changes the forward speed of teleop. Please drive carefully once the velocity is calibrated. If the forward speed when teleoping is too high, change the scale in human\_control for drive-speed in joy\_teleop.yaml.

Repeat the process until these values are within 2-3 cm.

Changing the software speed limit If you wish to change the top speed of the car and has already followed the instructions to change the hardware limit in the vesc firmware section. All you'll need to do is also change the speed\_min and speed\_max values in vesc.yaml. Note that the corresponding max speed in meters/second will be the max erpm value divided by the erpm gain. (e.g. speed\_max/speed\_to\_erp\_gain)

Tip

If you have any build and/or setup questions, post to the forum.
